About This Curriculum

Developed by Deep-C Ocean Science Educators Brittany Pace and Amelia Vaughan. Edited by Deep-C Coordinator Tracy Ippolito.

Deep Sea to Coast Connectivity: Utilizing scientific research to help students make connections between the theoretical nature of science and real world applications

This Gulf of Mexico multidisciplinary curriculum was developed around the five main research areas of the Deep-C Consortium: geomorphology, geochemistry, ecology, physical oceanography, and modeling. Each module includes five cumulative lessons, background information on the topic, relevant supplementary reading materials, a glossary, and an assessment. The purpose of this curriculum is to:

1. Provide teachers with a user-friendly curriculum that will introduce students to real-world applications of science as well as specific examples of environmental disasters – their impacts on ocean ecosystems as well as nature’s ability to and mechanisms for recovering from such events.
2. Synthesize some of the Deep-C Consortium’s research efforts, to date.
3. Increase Gulf of Mexico literacy.

It is our hope that this curriculum can serve as a model for future curricula developed based off of scientific research endeavors.

Contributing experts are listed throughout curriculum. Many thanks to these Deep-C researchers and students who edited, authored content, or assisted with development of the lesson plans.

Aligned with Ocean Literacy Principles and the Next Generation Sunshine State Standards

Next Generation Sunshine State Standards: CPALMS is the state of Florida’s official source for standards information and course descriptions. [http://www.cpalms.org/Public/](http://www.cpalms.org/Public/)

This curriculum is available online at [https://deep-c.org/education-and-outreach/gom-curriculum](https://deep-c.org/education-and-outreach/gom-curriculum)

# Table of Contents

## Introduction

### Geomorphology Module

LESSON PLANS:
- Geological Beginnings of the Gulf .......................................................... 7
- Mapping the De Soto Canyon ..................................................................... 15
- Seeping through the Seafloor .................................................................. 19
- Calculating Flow Rate ............................................................................. 23
- Sifting through Sediments ...................................................................... 30
- Remotely Operated Vehicles ................................................................... 35
Geochemistry Quiz ..................................................................................... 38
Geochemistry Glossary ............................................................................. 39

### Geochemistry Module

LESSON PLANS:
- Chemical Components of the Gulf ......................................................... 43
- Methane Mania ......................................................................................... 46
- Oiled Marine Snow ................................................................................ 49
- What Can We Learn from Sediment Profiling? ....................................... 52
- Oil Weathering and Fingerprinting ......................................................... 56
Geochemistry Quiz ..................................................................................... 62
Geochemistry Glossary ............................................................................. 63

### Ecology Module

LESSON PLANS:
- Setting the Baseline ................................................................................ 67
- Breaking It Down ..................................................................................... 70
- Go With the Flow: The Life of Plankton ................................................ 76
- Research Cruises in the Gulf ................................................................. 79
- Toxicity: Exposure to PAHs .................................................................... 83
Ecology Quiz ............................................................................................... 87
Ecology Glossary ......................................................................................... 88

### Physical Oceanography Module

LESSON PLANS:
- Oceanography Demonstrations .............................................................. 92
- Gravity Currents in the Gulf of Mexico .................................................. 97
- Tracking the Loop Current .................................................................... 101
- Go With the Flow: Designing Ocean Drifters ....................................... 104
- The SailBuoy’s Journey in the Gulf of Mexico ...................................... 110
Physical Oceanography Quiz .................................................................... 114
Physical Oceanography Glossary ............................................................. 115

### Computer Modeling

LESSON PLANS:
- Modeling 101 .......................................................................................... 120
- Oil Spill Models ....................................................................................... 124
- Making Predictions ................................................................................ 128
- Interpreting the Ocean through Color ................................................. 132
- Deep-C Map Viewer ............................................................................. 135
Computer Modeling Quiz .......................................................................... 137
Computer Modeling Glossary ................................................................. 138

Deep-C’s Gulf of Mexico Multi-disciplinary Curriculum for High School Science
Introduction

Deepwater Horizon Oil Spill

On April 20, 2010, a devastating explosion on the Deepwater Horizon oil rig ~41 miles off the coast of southeastern Louisiana resulted in the deaths of 11 people and triggered a leak at the Macondo well that released close to five million barrels of crude oil into the Gulf of Mexico. Clean-up personnel, scientists, and researchers from all over the country were among the first responders to this environmental disaster. They were tasked with stopping the oil flow, limiting exposure, and cleaning up as quickly as possible using the tools available to them (i.e., dispersants, top kills, in situ burning, oil booms). In the days and months that followed the accident, many of these first responders continued to play an active role in not only helping to mitigate the effects on site but also to offer valuable insight into where the oil and gas would go and the possible effects to the unique and varied Gulf of Mexico ecosystems. When the well was finally capped nearly three months later, many were left wondering what would happen next and what the long-term repercussions might be, both on the Gulf itself as well as the communities that rely on it.

Funding Research in the Gulf of Mexico

In May 2010, BP (the company who owned the rights to the oil from the Macondo well) committed $500 million over a 10-year period to create a broad, independent research program to be conducted at research institutions primarily in the Gulf Coast states. This program, the Gulf of Mexico Research Initiative (GoMRI), has since awarded numerous grants to research consortia, one of which was the Deep-C Consortium. The subsequent research has produced an exhaustive amount of data and provided many new insights into this under-studied ocean environment.

Deep-C Consortium: Deep Sea to Coast Connectivity in the Eastern Gulf of Mexico

Consortium Director: Dr. Eric P. Chassignet

Member and Affiliated Institutions: Florida State University (lead), Dauphin Island Sea Lab, Eckerd College, Georgia Institute of Technology, Leidos, Naval Research Laboratory at Stennis Space Center, Norwegian Meteorological Institute, University of Miami – RSMAS, University of North Florida, University of South Florida, University of West Florida, Valdosta State University, Woods Hole Oceanographic Institution.

Research Goal: To examine geomorphologic, hydrologic, and biogeochemical settings that influence the distribution and fate of the oil and dispersants while also evaluating and predicting the environmental consequences through integrated earth system and food web models. Research conducted by the Deep-C Consortium, a group of research institutions primarily located in the southeast U.S., provided an opportunity to develop an ocean science curriculum that brings current scientific research into K-12 classrooms.

During and after the Deepwater Horizon oil spill, Deep-C scientists investigated the consequences of petroleum hydrocarbon release in the deep Gulf of Mexico on living marine resources and ecosystem health, as well as nature’s response and surprising resiliency. The project sought to answer key questions, including:

1. What are the magnitudes, directions, and spatial and temporal scales of hydrodynamic processes that transport particles and dissolved substances (including oil, gas nutrients, solutes, and organisms) from the deep Gulf to the Florida panhandle shelf waters in the northeastern Gulf of Mexico? How are these influenced by canyon and shelf topography?

2. How does the transport of these particles and dissolved substances influence geochemical, biological, and demographic processes, including food web dynamics, across sea floor, pelagic, and near-shore ecosystems?
The Science of Oil in the Ocean: Origin and Chemical Composition
Exploring Oil Spills on a Molecular Basis

Adapted from National Ocean Science Bowl Professional Development Webinar Series 2015. This webinar, given by Dr. Chris Reddy, a marine geochemist at the Woods Hole Oceanographic Institution, explored how oil is formed, the composition and structure of oil and processes that affect oil. Listen to it at: http://nosb.org/learn/professional-development/guest-expert-dr-christopher-reddy/

Key Points

• All oils and oil spills are not the same. Oil contains thousands of different compounds with different chemical and biological characteristics.

• What happens to oil released into the environment and the subsequent impacts are dictated by the type of molecules comprised in the spilled oil.

• Released oil’s composition changes immediately due to weathering by different processes (e.g. evaporation and microbial degradation that occurs at different speeds and preference for different types of molecules in the oil).

• Where the oil is released is important.

• Investigation of oil spills reveal how nature responds to uninvited guests.

How is Oil Formed?

1. Algae and other organisms fall from the surface to the floor.
2. Debris is reworked by microbes and chemical reactions to form a geopolymer.
3. The geopolymer is “cooked and squeezed” into oil and gas.

Composition of Oil

Oil is made up of aromatic hydrocarbons, saturated hydrocarbons, and polar compounds. The majority of hydrocarbons in the Macondo well oil were of the saturated variety. Various processes, such as the types of organic matter, depth, temperature, pressure, and time cause differences in the molecular composition of oil. All oil molecules have a different make-up due to the different “personalities” of the many compounds.

Asphaltenes and resins are examples of larger molecules that make up oil and their behavior in the environment is unknown. Petroleum biomarkers, such as hopane, are molecular fossils, invaluable for capturing the “genetic” code of oil. They are the biochemical equivalent of the skeletal remains found at an archeological dig. They do not degrade very fast and can be used for oil fingerprinting to find the source.
Once crude oil is moved from its reservoir, it is then taken to a refinery. The oil is refined through a process where the carbon atoms are broken apart, forming “fractions.” For example: there are 5-10 carbons in gasoline, whereas diesel oils have 14 to 20 carbons. The spectrum of oil that can be released into the environment is vast.

**Natural Oil Seeps versus the Deepwater Horizon Oil Spill**

Hydrocarbons are a natural part of the Gulf ecosystem and are released into the ocean environment through a crack in the reservoir, called a natural seep – which creates an oil spill everyday (otherwise known as the “leaky faucet” effect). Specialized bacteria have evolved to eat oil near the seeps. Oil is a calorie rich material for microbes like butter is for us. When oil leaves the reservoir and enters the water column, it changes chemically and its fate is based on both its physical location as well as its molecular makeup.

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>Natural seeps in the Gulf of Mexico</th>
<th>Deepwater Horizon Disaster</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Duration</strong></td>
<td>Occurred everyday for 1000s of years</td>
<td>87 days in 2010</td>

**Processes that Affect Oil**

Spreading, drift, evaporation, dissolution, dispersion, emulsification, sedimentation, biodegradation, and photo oxidation are examples of weathering processes that affect a marine oil slick over time. Photochemical degradation is a function of the compound’s capacity to absorb sunlight. The rate of these processes varies. Deepwater Horizon oil traveled 5,000 feet to the surface and its chemical composition at the well when compared to the surface slick was very different. The most volatile compounds evaporated first. And microbes feasted on the released hydrocarbons (first the natural gas, and eventually the oil).
